Introductory Lectures: The Nature and History of Cognitive Science

Chapter 4: Philosophy's Convergence Towards Cognitive Science

By Dr. Charles Wallis Last revision: 9/24/2018

Chapter Outline

- 4.1 Introduction
- **4.2** The Scientific Explosion of the Early 20th Century
- **4.3** The Logical and Mathematical Explosion of the Early 20th Century
- 4.4 The Rise Logical Empiricism
- 4.5 Logical Behaviorism
- 4.6 Three Problems for Logical Behaviorism
- 4.7 Identity Theories: Reduction Through Reference Equivalence Rather Than Meaning Equivalence
- 4.8 Identity Theories: Type-Type Identity
- 4.9 Two Arguments For Type-Type Identity Theory
- 4.10 Identity Theories: Token-Token Identity
- 4.11 Functionalism
- 4.12 Computationalism
- 4.13 Property Dualism
- 4.14 Eliminative Materialism
- 4.15 Glossary of Key Terms
- 4.16 Bibliography

The 20th Century and the Semantic Twist

4.1 Introduction

Recall that ontological frameworks provide a general framework within which theorists specify domains of inquiry and construct theories to predict, manipulate, and explain phenomena within the domain. Once researchers articulate an ontological framework with sufficient clarity they begin to formulate and test theories. Chapter two ends with the suggestion that oppositional substance dualists face two major challenges in their attempt to transition from the articulation of an ontological framework to the formulation and testing of theories purporting to predict, manipulate, and explain mental phenomena. On the one hand, oppositional substance dualists have problems formulating theories providing explanations, predictions, and manipulations of the continual, seamless interaction between the mental and the physical. Philosophers often call this the interaction problem. On the other hand, the very nature of a mental substance--substance defined so as to share no properties with physical substance--gives rise to additional challenges. Specifically, how does one utilize the categories, types, and interrelationships of this mental substance to formulate theoretical mechanisms through which one can predict, manipulate, and explain the dynamic changes in mental phenomena? One might call this the mental mechanisms problem.

Chapter four looks at the question, "do monistic physicalists fare any better?" Recall, physicalist theories theories formulated within monistic physicalism--must meet the challenge of articulating theories specifying physical mechanisms that plausibly predict, manipulate, and explain how physical substance, physical properties, and/or physical processes give rise to mental properties and processes. As with oppositional substance dualism, one can group the challenges facing monistic physicalism into two general categories. First, theorists face what one might call the problem of physical categorization and mechanisms. Specifically, theorists must generate categories for mental phenomena that capture mental phenomena and which also can provide the basis for robust predictive, manipulative, and explanatory theoretic models. Some philosophers call one version of this problem the problem of qualia. The problem of qualia seems to arise because the central or criterial property of some mental states seems to involve qualitative experiences. Pain, for instance, seems to essentially involve painfulness. Pleasant feelings seem not to count as pains even if those states have the same typical causes and typical effects of painful mental states in humans. The problem of physical categorization and mechanism, as a result, seems to require that theorists somehow both (1) categorize pains using physicalistic categories so that the physicalistic category captures all and only painful states and (2) that those physical categories somehow give rise to theoretic models that explain the qualitative nature of pains. Second, monistic physicalists must solve the problem of demarcation. In other words, one's prima facie intuitive categorization judgments seem to indicate that the mental operates in a manner that precludes the inclusion of most physical objects and processes. To wit, every physical object has mass; but not every physical object has—even potentially—a mind. How can physicalistic categorizations and theories accommodate those intuitive categorization judgments? Or, should the monistic physicalist debunk the seeming differences between the mental and other physical objects, properties, and processes?

Recall that chapter three traces the development of scientific psychology from Wundt's voluntarism through psychological behaviorism. The chapter emphasizes how psychology develops an experimental tradition in

large part through the creative adaptation of approaches from astronomy, navigation, and physiology. Experimental traditions include a repertoire of operationalization techniques and devices as well as a repertoire of experimental designs, tools for data analysis, and an appreciation of experimental control. For instance, the chronoscope and chronometer allow precise measurement of reaction times and control hammer provides a mechanism for precise calibration of the chronoscope and chronometer to insure reliable inter-subjective measurements. The introduction and development of introspection and its associated experimental design from physiology—both through its successful adaptations and its failings provides psychologists with important lessons in experimental design. Of particular importance, psychologists realize the potential for experimenter and subject bias and the need for calibration techniques for operationalizations. This convergence of categorizations together with tractable and reliable operationalizations allows theorists to define a domain—learning and memory. Psychologists adopt and adapt experimental techniques that allow them to gain traction in the tasks of predicting, manipulating, and explaining mental phenomena in one aspect of one mental domain—learning and memory. Finally, the introduction of statistical techniques by Gustav Fechner¹ and others, especially their use by Hermann Ebbinghaus² helps theorists to analyze data with significant intersubjective variability and better measure the fit of theoretic models with data.¹⁻¹⁰ Ultimately, much more powerful statistical tools enter the experimental tradition from the works of Ronald Fisher¹¹⁻¹⁵ (e.x. null hypothesis testing,¹⁶ z-distribution,¹⁷ and frequentist inferential¹⁸ interpretations and methods generally), <u>William Gossett (aka student)</u>¹⁹⁻²¹ (e.x. <u>t-testing</u>²²), <u>Jerzy</u> Neyman²³⁻³³ (e.x. randomized experimental design, stratified sampling of significant subpopulations,²⁶ The Neyman-Pearson lemma for hypothesis testing,²⁵ and the confidence interval³⁴), Karl Pearson³⁵⁻³⁹ (e.x. Chisquared distribution⁴⁰), and Egon Pearson^{25, 29, 30, 33, 41-43} (e.x. The Neyman-Pearson lemma for hypothesis testing²⁵ and <u>Pearson's chi-squared test</u>⁴³). This confluence of descriptive and experimental elements gives rise to behaviorism in psychology.

This chapter and lecture outline what I call the "semantic twist." The semantic twist marks a dramatic shift in philosophic methodology and conceptualization that fundamentally alters the conception of the mind-body problem as well as the methodology within the philosophy of mind. It also marks a sharp, but often unrecognized division between philosophic approaches to the philosophy of mind. This chapter portrays the overt confluence from which the semantic twist emerges. It also outlines the covert division with philosophy of mind resulting from the semantic twist. Thus, the narrative begins with an historical exposition to facilitate an appreciation of the forces that ultimately culminate in the semantic twist. The exposition traces the dramatic developments in physics and chemistry as well as in logic and mathematics at the turn of the 20th century showing how these events inspire the rise of logical empiricism as a philosophical school and especially as a philosophy of science.

With the outlines of logical empiricism in place, the chapter and lecture trace the influence of those developments upon the philosophy of mind. Specifically, the chapter focuses on the confluence of psychological behaviorism, philosophy of language, and philosophy of science in formulating and advocating the philosophical doctrine known variously as logical behaviorism, philosophical behaviorism and analytical behaviorism. Analytical behaviorism represents a shift in the philosophic understanding of the mind-body problem as well as a corresponding shift in philosophic methodology.

Philosophers from Descartes until the semantic twist focus primarily upon two projects. First, philosophers emphasize developing and advocating various versions of the two most prominent ontological frameworks for

theorizing about the mind—oppositional substance dualism and monistic physicalism. Second, philosophers debate the relative potential of these two general types of ontological frameworks to give rise to adequate theoretical explanations of mental phenomena. After the semantic twist, most philosophers seek to understand how monistic physicalism can accommodate mental phenomena. Specifically, philosophers seek to advocate monistic physicalism by subsuming mental phenomena within the physical—not through positing physicalistic theories providing mechanistic explanations of mental phenomena—but through semantic reduction. In other words, philosophers adopt the project of demonstrating how ordinary, pre-theoretic talk about the mind expresses nothing over and above what one can express using physicalistic language. As a result, philosophers adopt the methodology of demonstrating the viability of monistic physicalism by showing that one can completely specify the meanings of ordinary language mental terms using only physicalistic categories. Since philosophers do not formulate physicalistic theories of mental phenomena, they rely primarily upon scientific results to provide the data upon which they base their reduction. Moreover, the new philosophic project does not directly involve transitioning from the articulation of an ontological framework to formulating and testing theories purporting to predict, manipulate, and explain mental phenomena. Hence, the new philosophic project is best understood as attempting to reduce one half of the framework of oppositional substance dualism—into the other half of the oppositional ontological framework—leaving only a monistic physicalism. The doctrine of logical behaviorism represents the first in a series of such attempts at semantic reduction. As future lectures indicate, the project of semantic reduction—or rejection thereof-occupies most of the philosophy of mind for the 20th century.

Ultimately, the doctrine of logical behaviorism succumbs to two central lines of criticism. On the one hand, critics like Putnam (in his early work) deny the viability of attempts to identify mental states and properties with the effects of those mental states and properties. These theorists essentially adopt a direct reference theory of meaning for mental terms in that they claim that the reference of mental terms such as belief or pain consists of the mental state itself regardless of its typical causes and effects. Often such theorists adopt a phenomenological essentialism regarding many of these terms. Specifically, such theorists look to conscious mental states—especially qualitative conscious experiences like pain--asserting that the conscious phenomenological experience provides a direct referential link to the state. Pains, on this line, are painful and this feature alone defines these states. For example, Thomas Nagel denies that science can formulate adequate theories of consciousness mental states because such theories cannot capture "what it is like" to have such mental states.⁴⁴⁻⁴⁹ Putnam adopts this line of argument in "Brains and Behavior"⁵⁰ when he presents a series of counterfactual thought experiments. Putnam suggests that one can intuitively judge that the mental states in his counterfactual examples count as pains despite being dissociated from their typical causes, their typical effects, or both.⁵⁰⁻⁵⁴ On the other hand, critics such as Chisholm adopt a descriptivist theory of reference for such mental state terms. Chisholm argues that attempts to define mental state terms like belief in terms of their typical overt physical causes and effects fails precisely because such states have no typical causes and effects absent their relationships to other mental state terms. Thus, argues Chisholm, one cannot define mental-state terms in isolation. Mental-state terms constitute a closed holistic lexicon or conceptual scheme.⁵⁵⁻⁵⁷ Ultimately, three features of mental states drive the rejection of logical behaviorism. First, the meanings of many mental terms seem essentially or importantly tied to qualitative subjective experience as opposed to overt behaviors. Thus, many people find the awfulness of pain essential to being in pain, but few find verbal demonstrations essential to being in pain. Second, many mental properties such as ennui (Listlessness or dissatisfaction associated with inoccupation or an absence of excitement) seem to lack

any definitive set of behavioral effects without seeming meaningless or less meaningful than other mental terms. Third, mental terms do not operate, for the most part, in isolation from one another. Rather, the interactions of mental states with other mental states mediate the connections between their typical behavioral causes and typical behavioral effects--even for those mental terms that appear to have more or less criterial overt behavioral causes and effects.

4.2 The Scientific Explosion of the Early 20th Century

The productive confluence of categorization, operationalization, and experiment at the beginning of the 20th century is not unique to scientific psychology. The end of the 19th century and the beginning of the 20th century witnesses the rise of a newly robust science in many fields. Physics and chemistry in particular witness a number of dramatic advances that tear apart the older orthodoxy. Within a period of approximately sixty years, from 1870 to 1930, the groundwork for atomic physics, atomic chemistry, quantum mechanics,

statistical mechanics, and space-time physics falls into place. For instance, the Austrian physicist <u>Ludwig</u> <u>Boltzmann</u> (1844–1906)^{58, 59} makes the first tentative moves towards statistical thermodynamics when, building on <u>Maxwell's (1871) work</u>,⁶⁰ Boltzmann publishes two famous papers. 1872 sees Boltzmann publish

"Further studies on the Thermal Equilibrium of Gas Molecules," (Weitere Studien über das Wärmegleichgewicht unter Gasmolekülen) in which he introduces his Boltzmann equation and his Htheorem.⁶¹ Boltzmann claimed the latter proved the second law of thermodynamics, while the former describes the statistical behavior of a thermodynamic system when not in a state of equilibrium. Boltzmann addresses potential difficulties with the 1872 paper in his 1877 paper, "Concerning the Relation of the Second Law of Proposition of the Mechanical Theory of Heat and the Theory of Probability Respectively the Theorems about the Thermal Equilibrium" (Über die beziehung dem zweiten Haubtsatze der mechanischen Wärmetheorie und der Wahrscheinlichkeitsrechnung respektive den Sätzen über das Wärmegleichgewicht).⁶² William Ramsay⁶³ and Lord Rayleigh (John William Strutt)⁶⁴ publish "Argon, a New Constituent of the Atmosphere" in 1895 marking the beginning of the discovery of noble gases and ultimately an expansion of the periodic table.⁶⁵ 1897 sees J.J. Thomson publish "Cathode Rays" in which he discovers the electron.⁶⁶ In 1901 Max Plank⁶⁷ publishes "On the Law of Distribution of Energy in the Normal Spectrum"⁶⁸ (Zur Theorie des Gesetzes der Energieverteilung im Normalspektrum) in which he introduces Plank's Law to calculate the electromagnetic radiation emitted by a <u>black body</u>⁶⁹ in thermal equilibrium at a given temperature. Plank's paper introduces the idea of quantum theory to physics. Albert Einstein's⁷⁰ miracle year in 1905 sees him publish four famous and foundational papers. "On a Heuristic Viewpoint Concerning the Production and Transformation of Light,"⁷¹ ("Über einen die Erzeugung und Verwandlung des Lichtes betreffenden heuristischen Gesichtspunkt") adapts Plank's work on black body radiation to explain the photoelectric effect.⁷² "Investigations on the Theory of Brownian Movement,"⁷³ ("Über die von der molekularkinetischen Theorie der Wärme geforderte Bewegung von in ruhenden Flüssigkeiten suspendierten Teilchen") describes the motion of pollen molecules in a liquid using statistical mechanics.⁷⁴ Importantly, Einstein demonstrates

the existence of atoms (the reality of which were debated) by showing how one can count them using an ordinary microscope. These two papers taken together lay the groundwork for the coming atomic physics and for quantum mechanics. "On the Electrodynamics of Moving Bodies," ("Zur Elektrodynamik bewegter Körper")⁷⁵ introduces what we now know as the theory of special relativity. More specifically, Einstein reconciles Maxwell's work in electromagnetism with classical mechanics by introducing the principle of relativity and the principle of the invariance of the speed light. Finally, in "Ist die Trägheit eines Körpers von seinem Energieinhalt abhängig?" ("Does the Inertia of a Body Depend Upon Its Energy Content?"), Einstein deduces his famous equation: $E = mc^{2.76}$ Einstein's former mathematics professor, <u>Hermann Minkowski</u>,⁷⁷ publishes "Space and Time"⁷⁸ ("Raum und Zeit") in 1908 in which Minkowski provides a space-time geometry to subserve special relativity. Ernest Rutherford⁷⁹ publishes "The Scattering of α and β Particles by Matter and the Structure of the Atom"⁸⁰ in 1911. In 1913 Neils Bohr publishes "On the Constitution of Atoms and Molecules" parts 1,⁸¹ 2,⁸² and 3⁸³ in which he modifies Rutherford's account within the framework of guantum mechanics. The resulting theory of atomic structure goes under several names; The Solar System Model, The Bohr-Rutherford Model, and The Bohr Model. In 1916 Einstein publishes, "The Foundation of the General Theory of Relativity,"⁸⁴ ("Die Grundlage der allgemeinen Relativitätstheorie") outlining the theory of general relativity⁸⁵ and completing the reconceptualization of gravitational physics. In 1919 Arthur Eddington⁸⁶ travels to the African island of Principe and provides photographic evidence to support general relativity (specifically, light bending around the sun) during the May 29, 1919 solar eclipse. 1925 sees Wolfgang Pauli publish "On the Connexion between the Completion of Electron Groups in an Atom with the Complex Structure of Spectra" (Über den Zusammenhang des Abschlusses der Elektronengruppen im Atom mit der Komplexstruktur der Spektren) in which he formulates the electron version of the Pauli Exclusion Principle.⁸⁷ Pauli's principle allows one to derive the properties of electron shells, both the orbits and the numbers of possible electrons in each orbit by demonstrating that no two electrons orbiting a single nucleus can have the same quantum state. Erwin Schrödinger publishes "An Undulatory Theory of the Mechanics of Atoms and Molecules" in 1926 in which his Schrödinger equation provides the mathematical framework for the wave model of atomic structure.⁸⁸ Warner Heisenberg⁸⁹ publishes "Quantum theoretical re-interpretation of kinematic and mechanical relations" (Über den anschaulichen Inhalt der guantentheoretischen Kinematik und Mechanik) in 1927 wherein he states the Heisenberg Uncertainty Principle.⁹⁰ Heisenberg's Uncertainty Principle states that the precision with which one can determine the position of some particle varies inversely with the precision with which one can determine its momentum. Thus, the period beginning in 1871 with Maxwell's book on heat and ending in 1927 with Heisenberg's paper on uncertainty sees a fundamental reformulation of thermodynamics, chemistry, and space-time physics as well as the birth atomic physics and quantum mechanics. Theoretical models move from exceptionless universal and deterministic laws towards statistical, probabilistic and relativistic models.

Finally, the American physicist <u>Percy Williams Bridgman</u>⁹¹ forwards the doctrine of <u>operationalism</u>^{92, 93} or operationism in his 1927 <u>The Logic of Modern Physics</u>.⁹⁴ The book and its author intend the doctrine for physics primarily, though it inspires a number of psychologists including the neo-behaviorist <u>Edward Chace</u> <u>Tolman</u>.⁹⁵ Bridgeman, inspired by general relativity and his own prowess as an experimental physicist, identifies theoretical concepts with the (single) unique procedure for their measurement. The doctrine remains somewhat ambiguous regarding its status as a theory of meaning, though it naturally lends itself to such an interpretation. Bridgeman interacts with two prominent early logical positivists, <u>Otto Neurath</u>^{96, 97} and Moritz Schlick⁹⁸ regarding his theory. Bridgman's work together with Einstein's strongly influence the development of philosophical thinking beginning in the 1920s and 30s.

4.3 The Logical and Mathematical Explosion of the Early 20th Century

The strides in logic and mathematics at the turn of the 19th century rival those in physics and the sciences. <u>Gottlob Frege</u>⁹⁹ publishes <u>Beariffsschrift</u>¹⁰⁰ in 1879. In <u>Begriffsschrift</u> Frege adopts <u>Georg Cantor's</u>¹⁰¹⁻¹⁰³ naïve set theory and presents the first rigorous axiomatized first- and second-order predicate logic including functions. Frege's takes as his ultimate goal the derivation of mathematics from logic, thereby reducing the former to the latter--a project called <u>logicism</u>.¹⁰⁴ Logicism represents one approach to the overarching project of providing an axiomatic treatment of all of mathematics on the model of Euclid's <u>Elements</u>. More precisely, the project then underway seeks to axiomatize basic arithmetic on the <u>natural numbers</u>.¹⁰⁵ In 1899 <u>David</u> <u>Hilbert</u>¹⁰⁶ publishes <u>Foundations of Geometry</u>¹⁰⁷ (Grundlagen der Geometrie) in which he offers an axiomatization of the geometry of Euclidean solids (3d Euclidean geometry). An American graduate

student, <u>Robert Lee Moore</u>,¹⁰⁸ develops and publishes an alternative axiomatization in 1907.¹⁰⁹ <u>Bertrand</u> <u>Russell</u>¹¹⁰ and <u>Alfred North Whitehead</u>¹¹¹ publish <u>Principia Mathematica</u>¹¹² in three volumes in <u>1910</u>,¹¹³ <u>1912</u>,¹¹⁴ and <u>1913</u>.¹¹⁵ Principia attempts to axiomatize mathematics (arithmetic on the natural numbers) in the logicist tradition. The development of second-order logic and the progress towards axiomatizing mathematics creates a sense that logic and mathematics is on the verge of completion. This sense continues until <u>Kurt Gödel</u>¹¹⁶ publishes "<u>On Formally Undecidable Propositions of 'Principia Mathematica' and Related</u> <u>Systems</u>"¹¹⁷ ("Über formal unentscheidbare Sätze der 'Principia Mathematica' und Verwandter Systeme") in 1931 in which he demonstrates that any axiomatic inference system capable of expressing the truths of basic arithmetic on the natural numbers must be either inconsistent or incomplete. Hilbert, an axiomatization enthusiast, famously suggests that mathematicians can save much of the benefits of axiomatization if one can demonstrate a general technique to identify unsolvable problems (the elements rendering any axiomatization incomplete). However, "An Unsolvable Problem of Elementary Number Theory" by <u>Alonzo Church</u>^{118, 119} and "On Computable Numbers, with an Application to the Entscheidungsproblem" by <u>Alan Turing</u>¹²⁰⁻¹²² demonstrate the impossibility of this last hope for the axiomatization project.

4.4 The Rise Logical Empiricism

Some philosophers conceive of the dramatic advances in science, mathematics, and logic as a lens through which one can see the outlines of a coherent picture of knowledge, science, and philosophy. Thus, in Vienna and in Berlin two groups of philosophers and scientists begin to extrapolate from the developments in science, math, and logic to frame a philosophy of science. These philosophers and scientists eventually articulate and advocate the philosophical doctrine of logical empiricism (also known as logical positivism). The individual members of this group of philosophers do not march in ideological lockstep. However, I will portray them homogeneously and in accordance with the earlier formulations of their doctrines for the purposes of exposition. The picture painted here does not distort the views of individuals too dramatically.

The logical empiricists hold four key doctrines. First, they hold what is now called the verification criteria of meaning. Second, they hold that scientific laws are universal, exceptionless statements. Third, they adhere to the doctrine of the unity of science, i.e., they hold that the structure of science consists in a nested hierarchy of axiom systems in which the higher, less fundamental sciences (the special sciences) consist of laws that one can reduce to one or more lower sciences by ideological reduction of the higher science terms to those of the lower science. Finally, the logical empiricists hold that the role of philosophy of science is to rationally reconstruct the sciences so as to reveal their logical structure, empirical foundations, and epistemic justification. I will outline each doctrine, its sources, and its implications within logical empiricism.

The logical empiricists from Vienna and Berlin include both philosophers and scientists. They view the explosion of scientific progress from the beginnings of the scientific revolution, and particularly the explosion at the beginning of the 20th century, as deriving primarily from tying theories and theoretical terms to rigorous empirical measurement and experimentation. Many of the logical empiricists view this practice of operationalism in the sciences as existing in stark contrast from the prevailing philosophy of German idealism. German idealism seeks to create philosophical systems through the process of dialectic and a priori speculation. The positivists view German idealism as stagnant and vacuous. Thus, the logical empiricists identify progressive, productive theorizing with the method of operationalization employed by the sciences, and come to adopt an interpretation of operationalization as their doctrine of meaning. Indeed, an integral part of the logical empiricist reductionist program in science as well as their rejection of metaphysical speculation lies in their doctrine regarding the meaning of theoretic terms. The earliest version of the positivist doctrine of meaning usually goes under the name of the <u>verifiability theory of meaning</u>,^{123, 124} the verificationist theory of meaning, or simply verificationism. This doctrine holds that the meaning of a proposition or theoretic term consists solely in the method of its verification. This doctrine along with the moniker of positivism traces back to Auguste Comte¹²⁵ (1798-1857), though positivists like Mortiz Schlick¹²⁶⁻¹²⁸ (1882-1936) and Otto Neurath^{129, 130} (1882-1945) also have extensive familiarity with operationalist the writings of Bridgeman.⁹⁴ The verificationist doctrine strikes out against vacuous metaphysical speculation in that verificationism implies that no statements have meaning unless one can cash-out their meaning in terms of

their conditions of verification. The early positivist writings often invoke this principle to critique philosophic problems as pseudo-problems. The verificationist theory of meaning also fits well with the notion of an interpretation function providing semantics for a formal language. Such interpretation functions act to pick out the class of objects in the domain that satisfy the predicate in the formal language.

The overall picture many logical empiricists embrace, at least early on, portrays science as a hierarchical set of axiomatic systems. Specifically, as a set of universal, exceptionless laws together with operational or bridge laws that serve to tie theoretic terms to the particular domain (see illustrative diagrams left) and/or to the theoretical terms of lower-level theories. This structure comes from the sciences themselves as well as from the logical and mathematical work by Hilbert, Frege, Russell, and Whitehead. Indeed, as noted above the work of these philosophers and mathematicians creates a great sense of optimism that mathematicians and

logicians will find and axiomatization for all of logic and mathematics. In this way, Euclid's influence reaches its full bloom—his *Elements* provides the paradigmatic structure for all of logic and mathematics. The logical empiricists make the final step in supposing that even the sciences should find their best expression as an axiom system in which the axioms are physical laws. Thus, the logical empiricists hold that the logical structure of each science is an axiom system. Moreover, these individual sciences cum axiom systems are unified; higher, less basic sciences like psychology or sociology reduce to lower level sciences and finally to the laws of physics. That is, the terms of higher level sciences reduce to the terms of successively lower-level theories. Ultimately, the theoretical terms of physics itself find their meaning through bridge laws that link the theoretical terms of physics to the experimental operations used to detect and/or measure the presence

or amount of the referents of those terms. As a result, experimental operations thereby define the referents of the theoretical terms of physics in an ontologically neutral observation language. This result, then, transfers throughout the entire hierarchy so that all theoretic terms of all sciences ultimately trace their meanings, either directly or indirectly, to conditions expressible in an ontologically neutral observation language. Logical empiricists refer to their hierarchy of axiom systems conception of the nature of scientific theories and the interrelationships between scientific theories as the unity of science.¹³¹ The unity of the sciences asserts that one can ultimately reduce all sciences to the most basic science, physics. That is, one can reduce the terms of sciences like elemental chemistry to the terms of atomic physics. Moreover, logical empiricists see a further benefit from such semantic reductions—the terminological reduction demonstrates that the laws in the reduced science follow from or merely represent special instances of more fundamental laws in the fundamental science.

The logical empiricists, especially those in Vienna, are deeply influenced by Ernst Mach,¹³² an Austrian physicist and philosopher, as well as by the works of Max Planck,⁶⁷ the German theoretical physicist who introduces the idea of quantum theory into physics. Mach also develops a philosophy of science and makes contributions to physiology and psychology. Indeed, the Vienna philosophers originally call their group Verein Ernst Mach (the Ernst Mach Society) in 1928, but they ultimately adopt the moniker Vienna Circle.^{133, 134} The group publishes their manifesto, Wissenschaftliche Weltauffassung. Der Wiener Kreis (The Scientific *Conception of the World. The Vienna Circle*) in 1929.¹³⁵ A kindred school with common members exists in Berlin, known both as the Berlin Group and the Berlin Circle.^{133, 136, 137} This group includes such luminaries as Paul Oppenheim¹³⁸ and Hans Reichenbach.^{137, 139} Both groups are strongly influenced by their common belief that human knowledge and especially science form part of a long evolutionary process creating a hierarchical set of sciences all of which ultimately reduce to physics. For instance, Rudolph Carnap's¹⁴⁰ classic work, *Der* Logische Aufbau der Welt (The Logical Structure of the World Pseudoproblems in Philosophy),¹⁴¹ provides readers with the most sophisticated and systematic attempt to reconstruct science from experience every written. Carnap casts science as a series of hierarchical axiom systems in which each high-level axiom system reduces to one or more lower-level systems and ultimately to observations framed in an ontologically neutral observation language. Similarly, Otto Neurath^{96, 97} edits multiple volumes of Foundations of the Unity of Sciences¹⁴² and International Encyclopedia of Unified Science.¹⁴³ These works set as their goal the organization and presentation of science as a unified body of knowledge. The logical empiricists do not suppose that the structure of a hierarchy of axiom systems actually represents the practice of scientists as they develop their theories. Rather, they suppose that this structure represents a rational reconstruction of the sciences that makes explicit and rigorous the logical structure and epistemic dependence of each science and the sciences as a whole.

The logical empiricists share a common disdain for metaphysical speculation and a desire to further human understanding through rigorous epistemological doctrines addressing methodological issues and minimizing ontological speculation. In many ways they turn the focus of philosophy of mind towards philosophy of science and issues of scientific methodology. The logical behaviorists follow the lead of methodological behaviorists in reexamining the proper understanding of mental properties and processes. However, logical behaviorists focus on theoretic terms and meaning giving rise to the semantic twist in the philosophy of science.

4.5 Logical Behaviorism

As discussed above, physics and chemistry advance at a blistering pace during the period from 1870 to 1930 resulting in dramatic reformulations of thermodynamics, chemistry, as well as space-time physics. Advances in the foundations of mathematics, formal logic, as well as statistics and probability not only introduce powerful formalisms and tools for scientific investigations; these advances provide insights into syntax and semantics for formal systems. These developments together with the first truly successful theoretical treatments of mental phenomena in psychology lead many philosophers of mind alter their focus from formulating and defending various ontological frameworks to understanding the relationship between scientific theories of the mind and ordinary conceptions of the mind. It is during the early 20th century that the emphasis in philosophy of mind—though still focused almost exclusively upon ontological issues—turns towards the developments in science for inspiration. Within philosophy itself a number of scientifically inspired general strategies emerge in the 20th century for trying to flesh-out a monistic physicalist framework.

This movement towards closer integration between philosophy and science also marks a shift in methodological emphasis.

During this period philosophers begin increasingly to think of theories not simply in terms of theoretical posits, but in terms of the relationships between categories with which scientists formulate their theoretic models and the terms of ordinary language and of perceptual experiences. As a result, during this time philosophical theorists become increasingly interested in semantic reduction. For instance, whereas earlier philosophers focus upon ontological frameworks, most 20th century strategies for offering monistic physicalist explanations involve directly identifying mental terms with physical terms. The underlying inference driving such identifications lies in the notion that by directly equating mental and physical terms one indirectly identifies the referents of those terms--mental phenomena and physical phenomena. In other words, 20th century philosophers locate the explanatory problem for the monistic physicalist in an inability to recognize or gather sufficient evidence for the co-referential nature of mental and physical terms.

Two general approaches to pursuing this general strategy emerge within philosophy during the first half of the 20th century. On the one hand, theorists try to identify the meaning of mental terms with sets of overt, observable, physical behaviors definitive of those terms. On the other hand, theorists seek to identify the reference of mental property, process, and entity terms with the reference of physical property, process, and entity terms with the reference of physical property, process, and entity terms through something akin to analytical reduction. The next section turns to this second strategy, often called type-type reductionism. The remainder of this section focuses upon the first strategy.

Theorists call the first systematic attempt to flush-out the first strategy for asserting that mental properties are just physical properties logical behaviorism. Logical behaviorism (also called analytical behaviorism and philosophical behaviorism) represents the first attempt to systematically address the difficulties for physicalism within the scientific framework of the time. It is important to note that philosophers of starkly different methodological orientations follow this line of theoretical speculation. Indeed, historians identify <u>Gilbert Ryle</u>^{144, 145} and <u>Carl Hempel</u>^{146, 147} as the two most prominent figures in logical and/or analytic

behaviorism. Ryle is a philosopher of language, particularly of ordinary language. Ryle holds that researchers can dissolve many philosophical problems through the correct analysis of the ordinary language terms that theorists employ the formulation of those problems. In his classic book, *The Concept of Mind*, Ryle argues extensively that mind-body oppositional dualism results from a category mistake—an incorrect use of language:¹⁴⁸

My destructive purpose is to show that a family of radical category-mistakes is the source of the double-life theory. The representation of a person as a ghost mysteriously ensconced in a machine derives from this argument. Because, as is true, a person's thinking, feeling, and purposive doing cannot be described solely in the idioms of physics, chemistry, and physiology, therefore they must be described in counterpart idioms. As the human body is a complex organized unit, so the human mind must be another complex organized unit, though one made of a different sort of stuff and with a different sort of structure. (p.18)

In contrast, Carl Hempel is a philosopher of science and a logical positivist/empiricist. Logical behaviorists like Hempel who embrace logical empiricism seek to build upon real progress by experimentalists like Pavlov, Watson, and Skinner as well as by scientists across a wide swath of the sciences. Like other logical positivists and empiricists Hempel believes that terms get their meanings through their conditions for verification, and that science provides one with the most rigorous and explicit methodological definitions of terms through operationalizations—the procedures that scientists use to detect and measure theoretical entities, properties, etc.. Hempel likewise believes in the unity of the sciences, and asserts that one can ultimately reduce all sciences to the most basic science, physics. That is, one can reduce the terms of sciences like elemental chemistry to the terms of atomic physics. Moreover, Hempel sees a further benefit from such semantic reductions—the terminological reduction demonstrates that the laws in the reduced science follow from or merely represent special instances of more fundamental laws in the fundamental science.

Most historians cite Gilbert Ryle's book, *The Concept of Mind* (1949)¹⁴⁸ as the first tract in logical behaviorism and assign Hempel's "<u>The Logical Analysis of Psychology</u>" (1935,1949)¹⁴⁹ to the second position. However, Hempel published his article, though in French, over 14 years earlier than Ryle's book. Both works have historical significance because they share a common shift of emphasis that continues to shape thinking about the mind in philosophy. Both Ryle and Hempel seek to defuse the seeming difficulties in understanding how mental properties arise from or are identical to physical properties by arguing that the meanings of mental terms are exhausted by overt behavioral dispositions. In other words, establishing monistic physicalism involves escaping referential opacity. Hempel tells readers,¹⁴⁹

All psychological statements which are meaningful, that is to say, which are in principle verifiable, are translatable into statements that do not involve psychological concepts, but only the concepts of physics. The statements of psychology are consequently physicalistic statements. (p.18)

Similarly, Ryle asserts,¹⁴⁸

In this chapter I try to show that when we describe people as exercising qualities of mind, we are not referring to occult episodes of which their overt acts and utterances are effects; we are referring to those overt acts and utterances themselves. (p.25)

While Hempel aims primarily to address scientific and ontological issues, Ryle sees his work in a different light. Ryle tries to provide an analysis of the concepts of ordinary language. Both philosophers, however, trace the seeming difficulties associated with the equation of mental processes and properties with physical properties and processes to an improper understanding of the true meanings of mental terms. Ryle asserts that,¹⁴⁸ This book offers what may with reservations be described as theory of mind. But it does not give new information about minds. We possess already a wealth of information about minds, information which is neither derived from, nor upset by, the arguments of philosophers. The philosophical arguments which constitute this book are intended not to increase what we know about minds, but to rectify the logical geography of the knowledge which we already possess. (p.7)

Additionally, Ryle's emphasis on intelligent behavior marks a differentiation between mental properties and non-mental properties which has come to serve as an important standard in the philosophy of mind, and which later allows for the initial explanatory focus of cognitive science on cognition. Specifically, philosophers differentiate between mental properties and states that are strongly (or even definitively) phenomenal in nature, called qualia or qualitative mental states, and mental properties or states that are primarily (or even definitively) intentional, called intentional states or propositional attitudes. Examples of the former (qualia) include pains, itches, seeing red, anger etc.. Examples of the latter (intentional states) include beliefs and desires. Intentional states may have some phenomenal aspects, but intentional states are importantly, even fundamentally representational. That is, intentional states represent objects, properties, relations and/or events in the world.

Thus, one can see that logical behaviorists—both the ordinary language variety and the logical empiricist variety--as seeking to understand the meaning and hence the reference of psychological terms like belief and desire in terms of the behaviors of intelligent creatures. Nevertheless, philosophers often misrepresent logical behaviorism as a unitary movement with a strongly shared set of background theoretical commitments. Logical behaviorists do share a commitment to science, and specifically to the promise of behaviorism in psychology. They also share a desire to capture the meanings of mental terms in behavioristic terms thereby identifying the referents of mental terms with the referents of physical terms.

However, logical behaviorism marks a significant point of divergence in the philosophy of mind. On the one hand, the logical empiricists give rise to an orientation in the philosophy of mind that seeks to understand the new and rapidly advancing sciences in terms of the theoretic posits, explanatory schemas, and methodological practices of those sciences. These theorists likely now identify themselves as philosophers of psychology or cognitive science. On the other hand, Ryle and other philosophers of language devote their efforts primarily to understanding the ascription conditions of ordinary language terms describing the mind, mental properties, and mental processes. These theorists, like Ryle himself, seek to understand the world by clarifying the ontological posits and theories implicit in ordinary language as used in everyday life. Ryle describes himself, for example, as philosophical cartographer.^{150, 151} Ryle likewise begins his discussion in *The Concept of Mind* by telling his readers that, "The philosophical arguments which constitute this book are intended not to increase what we know about minds but to rectify the logical geography of the knowledge we already possess."(p.1) ¹⁴⁸

4.6 Three Problems for Logical Behaviorism

No matter what motivations lead logical behaviorists to advocate their doctrine, logical behaviorism faces three significant difficulties. First, the meanings of many mental terms seem essentially or importantly tied to qualitative subjective experience as opposed to overt behaviors. Thus, many people find the awfulness of pain essential to being in pain, but few find verbal demonstrations essential to being in pain. A person paralyzed by curare will not exhibit the normal behavioral effects of pain when stabbed in the arm. However, it seems

improbable to suppose that such a person feels no pain. Likewise, actors really do suffer for their art according to logical behaviorists in that these actors actually suffer when overtly behaving as if they were suffering. Second, many mental properties such as aibohphobia (a fear of palindromes), ankylophobia (fear of stiff or immobile joints) and malaise (a vague feeling of discomfort, one cannot precisely identify, but which is often described as a sense that things are "just not right.") seem to lack any definitive set of behavioral effects. These terms do not seem meaningless or less meaningful than other mental terms, yet they do not exhibit a small group of overt behaviors that one might consider criterial of the state. Third, mental terms do not operate, for the most part, in isolation from one another. Rather, the connections between the typical behavioral causes and typical behavioral effects--even for those mental terms that appear to have more or less criterial overt behavioral causes and effects--are mediated by the interactions of mental states with other mental states. This last point finds emphasis in the work of Roderick Chisholm criticizing logical behaviorism and in the latter work of Hilary Putnam outlining functionalism.⁵²⁻⁵⁷ For instance, one cannot determine the causes and effects of your belief that this text is remarkably dry in isolation from your interest in the subject, your desire to do well in the class, etc.. If you love dry and boring texts, you may read all night. If you are hungry, your belief may result in your putting down the text to get a chocolate bar. The seeming interconnection between mental terms leads Putnam and others to formulate a new approach to theorizing called functionalism discussed later in this text. As Chisholm tells his readers:⁵⁷

Nevertheless, difficulties in principle seem to be involved when we attempt to extend the preparatorystimulus theory to human behavior. [Logical behavioristic reductions of mental terms to collections of stimuli and responses]

These difficulties concern the specification of the occasions upon which the appropriate fulfillments or disruptions must occur. According to our paradigm, these must be caused by the occurrence, or nonoccurrence, of the referent. But it is easy to think of elementary human sign situations where the appropriate events do not occur in the manner required. And to accommodate our definition to such cases, we seem required to make qualifications which reintroduce the intentional concepts we are trying to eliminate. [Other mental terms] (p.61)

Likewise, Chisholm later asserts that:55

...when we wish to describe anyone's believing, seeing, knowing, wanting, and the like, either (a) we must use language which is intentional or (b) we must use a vocabulary we don't need when we talk about non-psychological facts. (p.132)

Theorists explore the general difficulties facing approaches like Ryle's and Hempel's in the technical literature even before Ryle publishes *The Concept of Mind*. The verificationist theory of meaning and the difficulties involved in the inter-theoretic reduction that the logical empiricists initially advocate begins to attract the great minds of philosophy and science long before the 1950s. However, Putnam's "<u>Psychological Concepts, Explication, and Ordinary Language</u>"⁵⁴ (1957) and Chisholm's "<u>Intentionality and the Theory of Signs</u>" ⁵⁷ (1952) serve to make explicit and popularize the implications of these technical problems for logical behaviorism. Chisholm's classic paper adopts a descriptivist theory of reference for such mental state terms. Chisholm argues that attempts to define mental state terms like belief in terms of their typical overt physical causes and effects fails precisely because such states have no typical causes and effects absent their relationships to other

mental state terms. Thus, argues Chisholm, one cannot define mental state terms in isolation. Mental state terms constitute a closed holistic lexicon or conceptual scheme.⁵⁵⁻⁵⁷ In *Psychological Concepts* Putnam agrees that mental terms cannot be defined in isolation. He adopts a technical trick to specify a definite description of each mental term utilizing its interrelationships with other mental states and connections to typical causes and typical effects. Putnam's technique here as well as his shift from a direct reference to a descriptivist position utilizing definite descriptions will become clearer in the section on functionalism. For now, suffice it to say that Putnam claims that definite descriptions refer to mental states because mental states consist of all and only those things satisfying the definite description.

In "Brains and Behavior" Putnam straightforwardly denies the viability of attempts to identify mental states and properties with the effects of those mental states and properties, adopting a direct reference theory of meaning for mental terms according to which the reference of mental terms such as belief or pain consists of the mental state itself regardless of its typical causes and effects. Often such theorists adopt a phenomenological essentialism regarding many of these terms. Specifically, such theorists look to conscious mental states—especially qualitative conscious experiences like pain--asserting that the conscious phenomenological experience provides a direct referential link to the state. Pains, on this line, are painful and this feature alone defines these states. Putnam adopts this line of argument in "Brains and Behavior"⁵⁰ when he presents a series of counterfactual thought experiments in which, he suggests, one can intuitively judge that the mental states in counterfactual examples count as pains despite being dissociated from their typical causes, their typical effects, or both.⁵⁰⁻⁵⁴

These challenges together with the limitations and difficulties emerging in methodological behaviorism or simply behaviorist psychology combine to lead theorists to reject the behavior gambit. Monistic physicalist ontological frameworks for understanding the mind, mental properties, and mental processes must include more than mere overt behaviors and their probabilistic associations. By the later 1950s and early 1960s theorists actively seek to develop alternative methods of reducing mentalistic terms to the terms consistent with monistic physicalistic ontological frameworks for philosophy and psychology.

4.7 Identity Theories: Reduction Through Reference Equivalence Rather Than Meaning Equivalence

The last section and traces the developments that lead to the semantic twist. Specifically, sections outline how philosophers of mind alter their focus from formulating and defending various ontological frameworks to understanding the relationship between scientific theories of the mind and ordinary conceptions of the mind. The shift in emphasis comes in reaction to the dramatic advances in science, mathematics, logic, and especially psychology at the dawning of the 20th century. The emergence of logical empiricism as the predominant philosophy of science strongly shapes how philosophers understand the engine that drives the rapid advances in the sciences at the beginning of the 20th century. Specifically, the logical empiricists focus upon scientific categorizations. The doctrine of the verification theory of meaning postulates that categorizations drive scientific progress only when they get their meaning through operationalizations—through being tied to empirical phenomena through intersubjective procedures and observations. Likewise, intertheoretic reduction and the unity of science emphasize semantic reduction as the key element of intertheoretic equivalence. As a result, philosophers begin increasingly to think of theories not simply in terms of theoretical posits, but in terms of the relationships between categories of scientific theories and the terms of ordinary language and of perceptual experiences.

After the semantic twist, therefore, most philosophers seek to understand how monistic physicalism can accommodate mental phenomena. Specifically, philosophers seek to advocate monistic physicalism by subsuming mental phenomena within the physical. Philosophers do not posit physicalistic theories providing mechanistic explanations of mental phenomena. Rather, philosophers seek to demonstrate the viability of monistic physicalism through semantic reduction. In other words, philosophers adopt the project of demonstrating how ordinary, pre-theoretic talk about the mind expresses nothing over and above what one can express using physicalistic language. As a result, philosophers adopt the methodology of demonstrating the viability of monistic physicalism by showing that one can specify the meanings of ordinary language mental terms completely using only physicalistic terms. Since philosophers do not formulate physicalistic theories of mental phenomena, they rely primarily upon scientific results to provide the data upon which they base their reductionist theories. The underlying inference driving such identifications lies in the notion that by directly equating mental and physical terms one indirectly identifies the referents of those terms--mental phenomena and physical phenomena. In other words, 20th century philosophers locate the explanatory problem for the monistic physicalist in an inability to recognize or gather sufficient evidence for the co-referential nature of mental and physical terms.

The last chapter outlines one of two general approaches to pursuing this general strategy emerge within philosophy during the first half of the 20th century. On the one hand, theorists try to identify the meaning of mental terms with sets of overt, observable, physical behaviors definitive of those terms. Analytical behaviorism, discussed in the last sections and lectures represents the first instance of this strategy. On the other hand, theorists seek to identify the reference of mental property, process, and entity terms with the reference of physical property, process, and entity terms through something less than, but sufficiently akin to analytical reduction. The current chapter and lectures explore theories within this second strategy, often called type-type reductionism. The delineation of identity theories in this lecture and chapter will emphasize two important features of type-type identity theories. First, identity theories operate within the general framework of logical empiricism. Specifically, identity theories view intertheoretic reduction as proceeding through semantic reduction of higher-level theoretical categories to lower-level physical categories. Second, while analytic behaviorism views reduction as requiring meaning equivalence, identity theories seek a weaker identification--specifically, reference equivalence. In other words, identity theories do not seek to understand intertheoretic reduction through meaning reduction. Instead, identity theorists suppose that intertheoretic reduction requires only co-reference. Thus, type-type identity theory asserts that folk mental concepts prove co-referential with physiological concepts. In contrast, token-token identity theorists only require that tokens of mental types are also tokens of some or other physical type.

4.8 Identity Theories: Type-Type Identity

Theorists often call the successor to logical behaviorism type-type reductionism or type-type identity theory. Type-type reductionism identified types of mental entities, mental properties, and mental processes with specific types of physical entities, physical properties, and physical processes. For instance, one might identify the mental property of pain with the physical property of stimulated c-fibers. Historians generally credit the British philosopher and psychologist <u>U.T. Place</u> (1924-2000)¹⁵² and the Austrian philosopher <u>Herbert Feigl</u> (1902-1988)^{153, 154} as the sources of the modern identity version of type-type physicalism. Place's colleague J.J.C. Smart (1920-2012)¹⁵⁵ also adopts this position. The motivations of identity theorists stem in large part from (and build upon) difficulties with logical behaviorism. For instance, Place tells readers,¹⁵⁶ The view that there exists a separate class of events, mental events, which cannot be described in terms of the concepts employed by the physical sciences no longer, commands the universal and unquestioning acceptance amongst philosophers and psychologists which it once did. Modern physicalism, however, unlike the materialism of the seventeenth and eighteenth centuries, is behaviouristic. Consciousness on this view is either a special type of behaviour, 'sampling' or 'runningback-and-forth' behaviour as Tolman (1932, p. 206) has it, or a disposition to behave in a certain way, an itch for example being a temporary propensity to scratch. In the case of cognitive concepts like 'knowing', 'believing', 'understanding', 'remembering' and volitional concepts like 'wanting' and 'intending', there can be little doubt, I think, that an analysis in terms of dispositions to behave (Wittgenstein, 1953; Ryle, 1949) is fundamentally sound. On the other hand, there would seem to be an intractable residue of concepts clustering around the notions of consciousness, experience, sensation and mental imagery, where some sort of inner process story is unavoidable (Place, 1954). It is possible, of course, that a satisfactory behaviouristic account of this conceptual residuum will ultimately be found. For our present purposes, however, I shall assume that this cannot be done and that statements about pains and twinges, about how things look, sound and feel, about things dreamed of or pictured in the mind's eye, are statements referring to events and processes which are in some sense private or internal to the individual of whom they are predicated. (p.44)

Two central ideas define type-type identity: First, Place and Feigl hold that behavioristic and identity analyses

of mental terms do not exhaust the meaning of mental terms in ordinary language. That is, the new definitions of mental terms are not analytic--they do not capture the individually necessary and jointly sufficient conditions thought to dictate the meanings of ordinary terms. Place and Feigl hold that mental and physical terms pick out classes or kinds of things in virtue of their meanings, and that a significant part of the meaning of ordinary mental terms (as well as of the identity theorists new analyses of those terms) is synthetic--i.e., going beyond the definitional meaning, usually as a result of experience. Specifically, type-type reductionists hold that the various behavioral associations between mental terms and physical/bodily terms serve to provide an initial description of a physical (brain) state. One can modify the initial behavioral descriptions, to the extent necessary, as a result of experience. Such descriptions ultimately determine the physical state that corresponds to the mental state. The identification of the physical state with the mental state constitutes a synthetic discovery. Synthetic truths or discoveries differ from analytical truths or discoveries in that analytical truths follow from the meaning of the terms involved. Analytic truths equate statements or terms and have truth-values dependent upon the meanings of the constitutive terms and/or logical structure. Denying an analytic statement therefore results in a contradiction. For example, "All triangles are three-sided planar figures," is an analytic statement, so is "A square is a four-sided, regular planar figure." Likewise, "It's false that all unmarried human males are bachelors" is a contradiction, since by definition bachelors are unmarried men. Philosophers and logicians hold that the definitions and/or logical structure of analytic statements make them true. In contrast, synthetic truths do not follow merely from the meaning of the terms involved. Someone can negate a synthetic statement without a contradiction. For example, one can assert the negation of the statement that "Long Beach has a population of 360,000 people," without a contradiction. "It's false that Long Beach has a population of 360,000 people." is not a contradiction. For this reason, discovering the population of Long Beach is a synthetic discovery.

The synthetic nature of the discovery that brain states and processes prove identical to mental states and processes allows type-type theorists to side-step many of the objections raised by dualists. Place tells readers,

To say that statements about consciousness are statements about brain processes is manifestly false. This is shown (*a*) by the fact that you can describe your sensations and mental imagery without knowing anything about your brain processes or even that such things exist, (*b*) by the fact that statements about one's consciousness and statements about one's brain processes are verified in entirely different ways and (*c*) by the fact that there is nothing self-contradictory about the statement, *X* has a pain but there is nothing going on in his brain'. (p.45)

In other words, mental terms and physical terms share the same referent, but not the same meaning. Philosophers refer to terms that have the same referent, but which do not necessarily have the same meaning in all contexts as referentially opaque. Recall, two terms are referentially opaque if they refer to the same object or property, but one cannot intersubstitute the terms *salva veritate* (i.e. without changing the truth value of the statement) in many contexts—or instance belief descriptions. For example, people in northern latitudes can watch the northern lights (aurora borealis). They may proclaim that they see the northern lights or that the northern lights are beautiful. However, most would not say that they are watching the photonic discharge resulting from ionized nitrogen atoms regaining an electron and nitrogen and oxygen atoms returning to a grounded state from an excited state after collisions with charged particles (solar winds) traveling along the magnetic field lines of the Earth's magnetosphere. Nor would most observers likely say that the photonic discharge is beautiful. The difference, according to Place, between saying that the northern lights are photonic discharge and saying that the northern lights are beautiful is a logical feature:¹⁵⁶

'Consciousness is a process in the brain', on my view is neither self-contradictory nor self-evident; it is a reasonable scientific hypothesis, in the way that the statement' lightning is a motion of electric charges' is a reasonable scientific hypothesis. ... This logical feature may be described by saying that in both cases both the grammatical subject and the grammatical predicate are expressions which provide an adequate characterization of the state of affairs to which they both refer. (p.45)

Feigl expresses a similar point by telling readers that:¹⁵⁷

The identity thesis which I wish to clarify and to defend asserts that the states of direct experience which conscious human beings "live through," and those which we confidently ascribe to some of the higher animals, are identical with certain (presumably configurational) aspects of the neural processes in those organisms. ... we may say, what is had-in-experience, and (in the case of human beings) knowable by acquaintance, is identical with the object of knowledge by description provided first by molar behavior theory and this is in turn identical with what the science of neurophysiology describes (or, rather, will describe when sufficient progress has been achieved) as processes in the central nervous system, perhaps especially in the cerebral cortex. In its basic core this is the "double knowledge" theory held by many modern monistic critical realists. ... The "mental" states or events (in the sense of raw feels) are the referents (the denotata) of the phenomenal terms of the language of introspection, as well as of certain terms of the neuro[-]physiological language. For this reason I have in previous publications called my view a "double-language theory." But, as I have explained above, this way of phrasing it is possibly misleading in that it suggests a purely analytic (logical) translatability between the statements in the two languages. It may therefore be wiser to speak instead of twofold access or double knowledge. The identification, I have emphasized, is to be empirically justified, and hence there can be no logical equivalence between the concepts (or statements) in the two languages. (Section E ¶4 and 5)

4.9 Three Arguments For Type-Type Identity Theory

Place and Feigl, then, have two lines of argument for their identity theory. On the one hand, they argue that traditional dualist arguments like the argument from Leibniz's Law and the argument from introspection do not apply to the identities Place and Feigl advocate. Call these the inapplicability arguments. The inapplicability arguments go beyond merely claiming that different property ascriptions based upon conceptual analysis or counterfactual thought experiments suffer from referential opacity. Place and Feigl have a specific explanation for the referential opacity in such cases—only empirical investigation can establish co-reference in such cases. On the other hand, Place and Feigl present an argument from analogy with other historical examples of scientific reduction. Call these the reductive analogy arguments. Object color is really surface reflectance. Heat is mean kinetic energy. Sound is compression waves traveling through the atmosphere and pitch is just the oscillatory frequency of those waves. Lightening is just the sudden large-scale discharge of electrons between clouds. In sum, the history of scientific advancement repeatedly reveals instances in which physical objects, properties and processes that were originally known only phenomenologically came to be understood as phenomenological manifestations of purely physical objects, properties, and/or processes. Feigl tells readers that:¹⁵⁷

...the advance of scientific theories consists essentially in the reduction of a variety of originally heterogeneous observable facts and regularities to a unitary set of explanatory concepts and postulates. Customarily it is said, for example, that visible light is electromagnetic radiation (within a certain interval of wave lengths); that table salt is NaCl; that magnetized iron is an aggregate of iron atoms with a characteristic spin of certain of their electrons; that the transmitters of hereditary traits are the genes in the chromosomes of the germ cells; that (at least) short range memory traces are reverberating circuits in cerebral cell assemblies, etc. The "is" and the "are" in these sentences represent identities. But these identities differ in their mode of certification from the analytic identities of pure logic and mathematics.the identities established in the factual sciences are confirmed on the basis of empirical evidence.there are also such empirically ascertainable identities as those of Tully and Cicero, of William Thompson and Lord Kelvin, or of the evening star and the morning star. In the examples just given we have (extensional) identities of individuals labeled or uniquely described in two or more ways. (Section D, ¶2 &3)

A third argument for identity theory, or perhaps a third schema for an argument, simply notes that type-type identity theory renders mental terms consistent with monistic physicalism without denying the pre-theoretical meanings of mental terms. Indeed, theories of the mental can prove referentially consistent with monistic physicalist theories like evolution and neuroscience. Thus, one need not deny that "water" has a pre-theoretic phenomenal meaning as the tasteless colorless liquid that quenches thirst in order to understand that water has a chemical structure of H₂O. Moreover, by identifying the micro-referent of phenomenal water, scientists can now begin to explain, predict, and manipulate its known and unknown phenomenal properties.

4.10 Identity Theories: Token-Token Identity

In 1970, <u>Donald Davidson</u> (1917-2003)^{158, 159} proposes a new version of identity physicalism. Davidson starts his chapter, "<u>Mental Events</u>,"^{160, 161} by stating his motivation for the view,

Mental events such as perceivings, rememberings, decisions, and actions resist capture in the nomological net of physical theory. I start from the assumption that both the causal dependence and the anomalousness of mental events are undeniable facts. My aim is therefore to explain, in the face of apparent difficulties, how this can be. (p.138)

By nomological Davidson simply means law-like, and by anomalousness Davidson means not falling under exceptionless universal laws. Davidson thinks that the failure to find the simple type-type identifications theorists like Smart, Place, and Fiegl suggest together with the failure of psychology and sociology to generate universal exceptionless laws warrants a reconsideration of the type-type identity theory. In the quote above, Davidson tells readers that he takes the anomalousness of the mental as an undeniable fact. That is, Davidson holds that psychologists have not and cannot discovery universal exceptionless laws formulated in mentalistic categories.

The anomalousness of the mental presents a problem for Davidson because he accepts both (1) the monistic physicalistic framework and (2) the basic logical empiricist picture of laws and reduction in science. That is, Davidson holds that the dramatic success of sciences like physics proves the mechanistic and deterministic nature of the physical world as one describes it using the physical conceptual scheme. Specifically, scientists formulate laws using exclusively physicalistic descriptions. These physicalistic descriptions represent a conceptual scheme for describing the world. This conceptual scheme has proven itself capable of describing the world so that the sciences produce finite, exceptionless universal laws. Indeed, the collection of such laws forms a closed, complete deductive system. That is, given a complete physicalistic description of some state of the world, called a physical event, scientists can, at least in principle, deduce how the world will unfold by deducing the resulting physical event, i.e., the exclusively physicalistic description of the world resulting from the prior event.

The standard view of physical laws looks like the bottom of the diagram (below) for the reductionist view of science. However, what happens to the picture if the mental has exceptions to its laws? If one supposes that physical laws and bridge laws between the mental terms and the physical terms are exceptionless and universal, then an exception to a psychological law between S_1 and S_2 is an exception to the physical law between P_1 and P_2 . That is, all members of S_1 are members of P_1 and all members of S_2 are members of P_2 .

Thus, the exception to the psychological law between a token (member) of S_1 and token (member) of S_2 is also an exception to the physical law. The exceptionless bridge laws mean that the token (member) of S_1 is also a token (member) of P_1 and token (member) of S_2 is also a token member of P_2 . Thus, P_1 and P_2 violate the physical law just as S_1 and S_2 violate the psychological law.

Yet, Davidson famously argues that the anomalousness of the mental proves consistent

with a certain sort of physicalism in his paper. However, many people think that Davidson offers no reason to accept the anomalousness of the mental. In fact, Davidson does offer a reason for the anomalousness of the mental. Mental terms, like physical terms, form a conceptual scheme. Unfortunately, the conceptual scheme for the mental differs from the conceptual scheme for the physical. Davidson holds that the physical conceptual scheme has as its exclusive purpose conceptualization of the physical world for the purpose of

formulating and testing physical laws. In contrast, the primary purpose of the mental conceptual scheme consists in making attributions of mental terms so as to provide one with an understanding of other people. Specifically, Davidson argues that in order to understand the actions, beliefs, desires, etc. of a person one must understand the person as a rational agent. In other words, in so far as one cannot see the actions, thoughts, etc. of an individual as rational one cannot understand them. That is, the actions of the individual make no sense in the mental conceptual scheme if one cannot understand that person as acting in accordance with one's own standards of reasonableness. This emphasis on rational understanding can, and Davidson suggests does, often trump ascriptions that would support universal and exceptionless laws in psychology. Davidson feels that one can use psychological generalizations to explain and predict by relating mental events, i.e., descriptions of some state of the world using exclusively mentalistic terms. However, mental events, events one describes using mental terms, do not lend themselves to the expression of exceptionless universal mental laws because the mental conceptual scheme works to maximize one's ability to understand others, even if such understanding violates psychological laws. Hence, psychological laws, as mere heuristic generalizations, do not form a closed, complete deductive system.

But how can one avoid the seeming dire consequences of an anomalous mental realm? Specifically, Davidson wants to preserve three principles:¹⁶⁰

(1) Causal interaction occurs between the mental and the physical. (pp.137-138)

(2) If causal interaction occurs, then strict deterministic laws (universal and exceptionless) govern that interaction. Davidson refers to this property as "the Principle of the Nomological Character of Causality." (p.138)

(3) "The third principle is that there are no strict deterministic laws on the basis of which mental events can be predicted and explained (the Anomalism of the Mental)." (p.138)

How does Davidson solve his difficulty of rendering these principles consistent? The answer lies in his notion of the two conceptual schemes. Davidson holds that since the mental and physical conceptual schemes differ in their goals, no possible reduction of mental terms to physical terms exists. In other words, Davidson denies the possibility of exceptionless universal "bridge-laws"--laws relating mental descriptions of states of the world (mental events) to physical descriptions of states of the world (physical events). Though the argument seems complex, it is actually pretty straightforward. Physical laws are universal and exceptionless. Mental laws are neither universal nor exceptionless. As a result, if there were universal and exceptionless laws linking mental and physical events (bridge-laws), then those bridge-laws would provide a basis for universal exceptionless mental laws. Yet, there are no exceptionless universal mental laws. Conversely, if there were universal and exceptionless bridge laws would transfer those exceptions of mental laws into exceptions in physical laws. Yet, there are no exceptions bridge laws would transfer those exceptions of mental laws into exceptions in physical laws. Yet, there are no exceptions bridge laws would transfer those exceptions of mental laws into exceptions in physical laws. Yet, there are no exceptions bridge laws would transfer those exceptions of mental laws into exceptions in physical laws. Yet, there are no exceptions bridge laws would transfer those exceptions of mental laws into exceptions in physical laws. Yet, there are no exceptions to physical events (bridge-laws) and mental laws has exceptions in physical laws. Yet, there are no exceptions to physical laws. Hence, there can be no universal and exceptionless bridge laws.

What about the causation between the mental and the physical (principle 1) and the strict deterministic nature of all such causation (principle 2)? Easy, says Davidson; mental events are just descriptions of the

world using the mental conceptual scheme. Every mental event is just an event described using mental terms. But one can also describe that event using physical terms from the physical conceptual scheme. Thus, every token of a mental event is also a token of a physical event. The physical and mental descriptions might only hold for that token event, or the descriptions may prove more general. However, mental types do not reduce to physical types. So, some tokens of a particular type of mental event, call it M₁, will have token physical descriptions from different physical types than other tokens of mental events

from that type, .i.e. M_1 . Thus, despite the lack of mental-type to physical-type reduction, one can understand how token mental events are identical to token physical events—they are just different descriptions of the same event.

Moreover, since every token of a mental event has a physical event description, token mental events can causally interact with token physical events in a strict deterministic manner—the manner dictated by the strict deterministic law relating their physical event descriptions. Since physical event descriptions yield finite, exceptionless universal laws that combine to form a closed deductive system, all tokens of mental causal interaction with the physical fall under strict deterministic laws—just not laws using mental terms.

4.11 Functionalism

Not all philosophers see the failure to discover the mental type to physical type identities and robust psychological laws predicted by type-type identity theory, as the central difficulty for theorists like Feigl and Place. Putnam didn't suppose that psychology must formulate universal exceptionless laws. Instead, Putnam held that psychological laws would take the form of statistical generalizations. In two classic articles, "<u>Minds</u> and <u>Machines</u>"²⁷ (1960) and "<u>Psychological Predicates</u>²⁸ (1967) (later published as The Nature of Mental

States), Hilary Putnam (1926-2016) formulates a slightly different solution to the problems that motivate Fiegl and Place called functionalism. As noted earlier, philosophers like Plato and Aristotle seem to advocate theories that are roughly characterized as functionalist. However, Putnam puts the modern face on functionalisms. Putnam suggests that mental terms like pain and belief are not properly identified with some state that causes the behavioral indicators. Rather these mental terms refer to the functions that pain, belief, etc. play in the overall functioning of the organism. Specifically, Putnam suggested that physical causes of mental states (inputs), their causal relationships to other mental states, and the effects of mental states of physical states (outputs) served to definitively characterize mental states. Putnam identifies mental states with their functional characterizations, in part because, he argues, systems may come to have different states

Diagram depicting the relationships important for characterizing mental states according to functionalism. These theorists hold that a mental state is the type of state it is in virtue of its place in one's overall cognitive economy (one's causal nexus as described by an accurate theory), specifically the physical causes of mental states (inputs), their causal relationships to other mental states, and the effects of mental states of physical states (outputs).

from a physiological perspective that have the same functional characterization. Such states, Putnam suggests, would be instances of the same psychological type, but instances of different physiological types. For example, if you believe that lobsters feel pain, you won't find type identity theory very satisfying because lobsters lack a

centralized nervous system, and hence, lack the structures associated with pains in humans. This idea came to be known as multiple realizability. Ned Block (1942-) and Jerry Fodor (1935-) publish "<u>What Psychological</u> <u>States are Not</u>"²⁹ in 1972, further articulating and defending functionalist theory. Even as Putnam articulates a synthetic, empirical functionalism, D. M. Armstrong (1926-) published his *A Materialistic Theory of the Mind*³⁰. Like Putnam, Armstrong argued that mental states were best characterized by descriptions incorporating physical causes of mental states (inputs), their causal relationships to other mental states, and the effects of mental states of physical states (outputs). However, unlike Putnam, Armstrong views these descriptions as strict analyses of the concepts of our ordinary language terms that give the individually necessary and jointly sufficient conditions that the terms meaning. Finally, like Place, Armstrong viewed these descriptions as picking out the physical state that corresponded to the mental state.

4.12 Computationalism

The connection between functionalism and computation as well as computers traces back to Putnam's early formulations. However, starting in the late 1970s philosophers converge upon the basic explanatory schema of the CTC/RTI both as a theory of cognition and cognitive states, and as a theory of explanation and explanatory methodology. Work by Ned Block (1942-) ["Introduction: What is Functionalism"³¹ and "Troubles with Functionalism"³²], Robert Cummins (1948-) ["Functional Analysis"³³ and *The Nature of Psychological Explanation*³⁴], Dan Dennett (1942-) [*Brainstorms*³⁵], Jerry Fodor (1935-) ["Special Sciences (Or: The Disunity of Science as a Working Hypothesis)"³⁶ *The Language of Thought*³⁷], and John Haugeland (1945-) ["Semantic Engines"³⁸ and *Artificial Intelligence: The Very Idea*³⁹] further articulate the structure of explanations in Cognitive Science. The resulting picture is beautifully articulated in their work. The last few of these introductory lectures, outlines the salient features of this picture.

4.13 Property Dualism

The explanatory schema and methodology outlined in these introductory lectures does not have homogeneous acceptance across all researchers in all the core disciplines of cognitive science. Two other views emerge in the late 1970s and 1980s. One position that emerges stems from the difficulties faced by functionalism, specifically functionalism's inability to easy capture the qualitative aspects of consciousness, also called qualia. Thomas Nagel (1937-) publishes "What it is like to be a Bat?,"⁴⁰. Frank Jackson (1943-) publishes "What Mary Didn't Know,"⁴¹ and David Chalmers (1966-) publishes "Absent Qualia, Fading Qualia, Dancing Qualia"⁴² and *The Conscious Mind: In Search of a Fundamental Theory*.⁴³ Each of these works suggest, for different reasons than Armstrong, that some if not all mental states are not physical states as traditionally understood. Nagel and Chalmers both take a page from Spinoza, and suggest that the notion of physical

substance should be expanded to allow for both the traditional physical properties and mental properties. This view is known as property dualism.

4.14 Eliminative Materialism

The final view we'll consider in this lecture, eliminative materialism has a amorphous history. The basic idea behind the view had been in the air for a long time. Historians often attribute it to James Cornman's " On the Elimination of 'Sensations' and Sensations"⁴⁴ (1968). Cornman himself attributes it to WVO Quine's *Word and Object*⁴⁵(1960). William Lycan and George Pappas attribute it to Richard Rorty's "<u>Mind-Body Indentity, Privacy</u> and Categories"⁴⁶(1965). However, few doubt that eliminative materialism rose to prominence and came to be associated with the University of California, San Diego and three philosophers who spent the early 1980s there. It is these three thinkers as well as Daniel Dennett that gave the view its modern formulation, and its most rigorous defense. As the seventies end and the eighties begin, Paul Churchland, Patricia Churchland, Daniel Dennett, and Stephen Stich publish papers outlining and defending the view that our ordinary mental terms constitute a psychological theory--folk psychology. Eliminativists hold that our theoretical terms pickout (or fail to pick-out) real objects or properties in virtue of the role these terms play in our theories. In other words, theoretical terms pick-out (or fail to pick-out) real-world objects in virtue of that the theory asserts about those objects. For instance, Phlogiston theory tells us that flammable objects contain phlogiston, the fire stuff. Object combustion, according to the theory is just the process of phlogiston leaving the object. So, the phlogiston theory picks out a real-world object, just in case there is something in the real world that satisfies the properties and relations attributed to phlogiston by the theory. In the case of phlogiston, scientists discover that the net byproducts of combustion have a greater mass than the original material. This finding, among others, suggests that there is no phlogiston, i.e., there is no real world object that plays the role of leaving a combustible material when it burns. Similarly, if a theory proves inadequate to explain phenomena, then we ought to suppose that the theory is false, and the objects it posits do not exist.

Folk psychology, the eliminativists argue, is both explanatorily inadequate and, taken as whole, radically false about the states and properties of the mind. For instance, consider the following *prima facie* inadequacies of our ordinary folk psychological understanding of our minds: Nothing about our ordinary notion of consciousness explains why we have to spend approximately eight hours a day unconscious. Nor does the folk psychological concept of consciousness explain what happens when we go from being conscious to being unconscious, or why we can't simply will ourselves to be unconscious. Likewise, folk psychology proves woefully inadequate to explain why people develop illnesses like schizophrenia. As Paul Churchland observes:⁴⁷

In sum, the most central things about us remain entirely mysterious from within folk psychology. And the defects noted cannot be blamed on inadequate time allowed for their correction, for folk psychology has enjoyed no significant changes or advances in well over 2,000 years, despite its manifest failures. (p.46)

Similarly, Dennett⁴⁸ notes that our ordinary notion of pain as a unified experience looks prima facie false when one notices that the painfulness and the adverseness or awfulness of pain can, and in many cases do, appear in isolation from one another. For example, people given morphine prior to their operations often report

feeling the painful sensations without the adverse or awful aspects when prodded by the surgeon. Similarly, the awfulness of pain can be diminished by concentrating on the painfulness aspect of the qualitative experience.

As a result, eliminativists argue, mental properties as conceived by our folk psychology do not actually exist. This position has come to be known as eliminative materialism. Daniel Dennett's "<u>Why You Can't Make</u> a <u>Computer that Feels Pain</u>,"⁴⁸(1978) and <u>Consciousness Explained</u> ⁴⁹(1991), Paul Churchland's "<u>Eliminative</u> <u>Materialism and the Propositional Attitudes</u>"⁵⁰(1981), "<u>Reduction, Qualia, and the Direct Introspection of</u> <u>Brain States</u>,"⁵¹(1985), Stephen Stich's *From Folk Psychology to Cognitive Science: The Case Against Belief* ⁵²(1982), and Patricia Churchland's *Neurophilosophy: Toward a Unified Science of the Mind-Brain*⁵³ (1986) are perhaps the best known and most definitive statements of the view. It is important to note that the contemporary statement of the view does not deny the existence of any kind of mental states or properties. Rather, it denies the existence of the mental states and properties found in and understood through our ordinary concepts. Thus, while Paul Churchland and Daniel Dennett deny that pains exist, they do not deny that we experience adverse sensations when stuck with a pin. They deny that a state or property exists that satisfies the description ingrained within our ordinary mental concepts of the typical causes and effects of pains.

A final point to note with regard to eliminative materialists; the staunchest advocates of eliminative materialism are also among the most influential architects of the contemporary understanding of computationalism. In other words, denying that an adequate explanation of cognition and cognitive capacities will include our ordinary folk concepts (together with their alleged referents) is consistent with asserting that such explanations will take the form of computational/representational theories.

In the next lecture we turn to the historical development of physiology. One might think that physiology marks a detour out of the core disciplines of cognitive science. However, physiology makes two significant connections in the history of cognitive science. First, psychology has two parent disciplines; philosophy and physiology. Philosophy introduces the "big questions" regarding the nature and operations of the mind. Physiology-particularly the early physiology of the nervous system--marks the beginnings, not only of neuroscience, but also of the introduction of experimental methodology to the study of the mind. Second, neuroscience develops out of physiology.

4.15 Glossary of Key Terms

Dualism: According to Wallis, dualism refers to the supposition within an ontological framework of exactly two fundamental categories to fill a specific role. Substance dualism provides an example of a dualistic view regarding the number of categories of substance in that it hold that both mental and physical substance exist. Dualisms with regard to causation appear in many ontological frameworks. For instance, in Chinese philosophy the concept of yin and yang—complementary interacting forces represents a dualism of forces.¹⁶²

The Interaction Problem: Everyday experience seems to indicate that the mind and the body constantly causally interact with one another. If you hit your finger with a hammer, that physical occurrence seems to trigger a mental feeling of pain. Likewise, the mental decision to hammer a nails seems to cause one's body to act. The oppositional substance dualist seems to face a difficult problem when trying to formulate dynamic models of phenomena suggesting mental/physical causation: How do two substances having such antithetical properties causally interact with one another? For instance, where would causal interaction occur given that mental substance has no extension?

Monism: According to Wallis, monism refers to the supposition within an ontological framework of a single fundamental category to fill a specific role. Thus, both monistic idealism and monistic physicalism provide examples of monistic views regarding the number of categories of substance. Unified field theory would constitute a monistic view regarding the number of categories of force in physics. Unified field theory seeks to replace the current four fundamental forces with a single force.¹⁶³

Monistic Idealism (Idealism): Monistic idealism holds that mental substance constitutes the only entity in the universe. Berkeley stands out as one of the most influential monistic idealists. Berkeley holds that all mental and physical phenomena consist of nothing but ideas in minds.^{164, 165}

Monistic Physicalism (Physicalism or Materialism): Monistic Physicalism holds that physical substance constitutes the only entity in the universe. Therefore, monistic physicalists hold that all phenomena—both physical and mental phenomena—result from modifications or permutations of physical substance. The Presocratic philosophers <u>Leucippus</u>¹⁶⁶ (and his pupil <u>Democritus</u>¹⁶⁷ (460-370 BCE) founded one school of monistic physicalism--atomism.¹⁶⁸ Greek atomists like Democritus hold that the universe consists of atoms and the void.

Oppositional Dualism: According to Wallis oppositional dualism refers to the supposition within an ontological framework of two fundamental categories to fill a specific role where the framework assigns opposite or fundamentally different properties to each category. Plato's dichotomy between the sensible and the intelligible introduces a dualism of ontological kinds sharing no essential properties—an oppositional dualism. For Plato the sensible realm consists of entities that are changeable, divisible, and capable of manifesting contradictory properties. In contrast, the intelligible realm consists of immutable, indivisible entities that never manifest contradictory properties.

Oppositional Substance Dualism: According to Wallis oppositional substance dualism to refers to those substance dualisms that assign opposite or fundamentally different properties to each kind of substance. Thus, Descartes substance dualism counts as an instance oppositional substance dualism in that Descartes defines mental and physical substance in terms of opposing properties. For example, physical substance is divisible while mental substance is not divisible.

Pluralism: According to Wallis, pluralism refers to the supposition within an ontological framework of two or more fundamental categories to fill a specific role. For example, the current four fundamental forces in physics represents a pluralistic view regarding the number of categories of force in that physicists hold that the four fundamental forces, gravitation, electromagnetism, strong nuclear force, and weak nuclear force, constitute the set of forces necessary to explain physical phenomena. Similarly, <u>Anaxagoras</u>¹⁶⁹ (500-428 BCE) of Clazomenae (an area in Turkey in Asia Minor) appears as the ultimate substance pluralist, holding that all types of materials—from milk to gold—constitute distinct eternally existing substances with their respective characteristics.¹⁷⁰⁻¹⁷² Empedocles¹⁷³(490-430 BCE) of Agrigentum (now known as the city of Agrigento in Sicily) appears likewise to adopt a pluralism. Empedocles posits the existence of the basic four elements (earth, air, fire, and water) together with two forces, love for combining and strife for separating these elements to create other materials.^{170, 174}

The Problem of Demarcation: Monistic physicalists must also provide a plausible solution or dissolution to the problem of a demarcation criterion. In other words, one's *prima facie* intuitive categorization judgments

seem to indicate that the mental operates in a manner that precludes the inclusion of most physical objects and processes. To wit, every physical object has mass; but not every physical object has—even potentially a mind. How can physicalistic categorizations and theories accommodate those intuitive categorization judgments? Or, should the monistic physicalist debunk the seeming differences between the mental and other physical objects, properties, and processes?

The Problem of Physical Categorization and Mechanism: Monistic physicalists face what one might call the problem of physical categorization and mechanisms. Specifically, theorists must generate categories for mental phenomena that capture mental phenomena and which also can provide the basis for robust predictive, manipulative, and explanatory theoretic models. Some philosophers sometimes call one version of this problem the problem of qualia. The problem of qualia seems to arise because the central or criterial property of some mental states seems to involve qualitative experiences. Pain, for instance, seems to essentially involve painfulness. Pleasant feelings seem not to count as pains even if those states have the same typical causes and typical effects of painful mental states in humans. The problem of physical categorize pains using physicalistic categories so that the physicalistic category captures all and only painful states and (2) that those physical categories somehow give rise to theoretic models that explain the qualitative nature of pains.

Substance Dualism: Substance dualism posits the existence of two fundamental kinds of substance-- mental substance and physical substance. In general, substance dualists assert the existence of two fundamental kinds of substances on the grounds that a single substance cannot explain both mental and physical phenomenon. Thus, substance dualists claim that all mental phenomena result from modifications or permutations of mental substance. All physical phenomenon, in contrast, result from modifications or permutations of physical substance. Importantly, substance dualism holds that mental substance and physical substance are irreducible to one another. Rene Descartes probably stands out as the most famous substance dualist.¹⁷⁵

Substance Monism: Substance monism holds that only one type of substance exists; there is only one kind of entity in the universe. According to substance monism all of the universe's phenomena-- both mental and physical phenomena--result from some sort of modification or permutation of a single kind of entity. The two most common versions of substance monism are monistic physicalism (also called physicalism or materialism) and monistic idealism (also called idealism).

The domain hypothesis: According to Wallis the domain hypothesis refers to the often tacit theoretical supposition that some diverse set of phenomena, in fact, form a common set of interrelated phenomena (i.e., a domain). In this chapter Wallis suggests that the development of the Greek concept of the soul ultimately leads thinkers to formulate a domain hypothesis with regard to mental processes and properties. That is, theorists ultimately come to suppose that mental processes and properties form a common, interrelated set of phenomena—a domain.

The Common Locus Hypothesis: According to Wallis theorists forward the common locus hypothesis whenever they come to suppose that a set of interrelated processes and properties have a common locus—that there is a single thing that has the properties and where the processes occur. In this chapter Wallis suggests that the development of the Greek concept of the soul ultimately leads thinkers to formulate a

common locus hypothesis with regard to mental properties and processes. That is, theorists ultimately come to suppose that there is a single entity—the mind—that has mental properties and in which mental processes occur.

The Mental Distillation Hypothesis: The process of property and process accretion through which theorists come to identify the contemporary mental processes and properties with the soul also infuses the notion of the soul with other, non-mental properties. Once Greek thinkers have come to accrete the set of contemporary mental properties and processes to the soul, they must also disentangle other properties and processes from that entity. Wallis calls this the mental distillation hypothesis.

The Mental Mechanisms Problem: The oppositional substance dualist seems to face a second difficult problem when trying to formulate dynamic models of phenomena suggesting mental causation: How does mental substance causally change? The typical mechanical properties of physical substance, such as position and number, used in dynamical physical theories are, by definition absent from mental substance. So, to what properties does one appeal when formulating dynamic theories? How does one utilize the categories, types, and interrelationships of this mental substance to formulate theoretical mechanisms through which one can predict, manipulate, and explain the dynamic changes in mental phenomena?
